Homework 1

1. Moore's law. The figure and table below show the number of transistors N in 13 microprocessors, and the year of their introduction.

Year # of transistors 1971 2,250 1972 2,500 1974 5,000 1978 29,000 1982 120,000 1985 275,000 1989 1,180,000 1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000 2003 410,000,000		
1972 2,500 1974 5,000 1978 29,000 1982 120,000 1985 275,000 1989 1,180,000 1993 3,100,000 1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000	Year	# of transistors
1974 5,000 1978 29,000 1982 120,000 1985 275,000 1989 1,180,000 1993 3,100,000 1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000	1971	2,250
1978 29,000 1982 120,000 1985 275,000 1989 1,180,000 1993 3,100,000 1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000	1972	2,500
1982 120,000 1985 275,000 1989 1,180,000 1993 3,100,000 1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000	1974	5,000
1985 275,000 1989 1,180,000 1993 3,100,000 1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000	1978	29,000
1989 1,180,000 1993 3,100,000 1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000	1982	120,000
1993 3,100,000 1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000	1985	275,000
1997 7,500,000 1999 24,000,000 2000 42,000,000 2002 220,000,000	1989	1,180,000
1999 24,000,000 2000 42,000,000 2002 220,000,000	1993	3,100,000
2000 42,000,000 2002 220,000,000	1997	7,500,000
2002 220,000,000	1999	24,000,000
, ,	2000	42,000,000
2003 410,000,000	2002	220,000,000
	2003	410,000,000

The plot gives the number of transistors on a logarithmic scale. Find the least squares straight-line fit of the data using the model

$$\log_{10} N \approx \theta_1 + \theta_2(t - 1970)$$

where t is the year and N is the number of transistors. Note that θ_1 is the model's prediction of the log of the number of transistors in 1970, and 10^{θ_2} gives the model's prediction of the fractional increase in number of transistors per year.

- (a) Find the coefficients θ_1 and θ_2 that minimize the RMS error on the data, and give the RMS error on the data. Plot the model you find along with the data points.
- (b) Use your model to predict the number of transistors in a microprocessor introduced in 2015. Compare the prediction to the IBM Z13 microprocessor, released in 2015, which has around 4×10^9 transistors.
- (c) Compare your result with Moore's law, which states that the number of transistors per integrated circuit roughly doubles every one and a half to two years.

The computer scientist and Intel corporation co-founder Gordon Moore formulated the law that bears his name in a magazine article published in 1965.

- 2. Sequential outlier removal. Throughout this problem, you'll use the data U, v, found in fitting_outliers.json. Here, $U \in \mathbf{R}^{n \times 1}$, so there is only one (nonconstant) feature. This one feature is already (nearly) standardized, so you do not need to standardize it. The data matrix X will have two columns, the constant feature one and the feature given in U. Also, there is enough data that you do not need to use any regularization.
 - (a) Fit a least squares model to the dataset above and plot the data points and straight-line fit. Describe what you observe.
 - (b) Sequential outlier removal. Find the data point with the largest loss and label it as an outlier. Remove this point from your data set and fit the model again to this new dataset (which has one fewer data point). Continue doing this until your θ stops changing too much (say, the change between the components of the previous θ and the current one is no more than .01).

Show a few of the intermediate fits and the final fit plotted against the data points. Describe what you observe.

3. Minimizing a squared norm plus an affine function. Minimizing a squared norm plus an affine function. A generalization of the least squares problem adds an affine function to the least squares objective,

minimize
$$||Ax - b||^2 + c^T x + d$$

where the n-vector x is the variable to be chosen, and the (given) data are the $m \times n$ matrix A, the m-vector b, the n-vector c, and the number d. We will use the same assumption we use in least squares: The columns of A are linearly independent. This generalized problem can be solved by reducing it to a standard least squares problem, using a trick called completing the square. Show that the objective of the problem above can be expressed in the form

$$||Ax - b||^2 + c^T x + d = ||Ax - b + f||^2 + g$$

for some m-vector f and some constant g. It follows that we can solve the generalized least squares problem by minimizing ||Ax - (b-f)||, an ordinary least squares problem with solution $\hat{x} = A^{\dagger}(b-f)$.

Hints. Express the norm squared term on the right-hand side as $||(Ax - b) + f||^2$ and expand it. Then argue that the equality above holds provided $2A^T f = c$. One possible choice is $f = (1/2)(A^{\dagger})^T c$. (You must justify these statements.)
